

1. What was the most difficult part of interpreting the original author's logic?

The overall purpose and logic of the system was clear and straightforward, the most difficult was actually executing it and connecting it to the database. It was challenging to translate theoretical database relationships into PHP queries that handle document routing and status updates without data conflicts. It's difficult not having the original code for reference and just the ERD and a few book pages.

2. What technical challenges did you face during recreation?

The biggest challenges were making the design look nice while still being functional. I struggled most with CSS to get the buttons, spacing, and alignments right. When I change something even a little bit there would be errors and I kept on encountering where when I updated something the button would not work entirely. I also ran into some bugs where parts of the form were showing up twice or the text was overlapping because the design didn't fit. We also have troubles when pushing because of the merging problem.

3. How would you improve this module further?

I would like to add a user authentication system with role-based access control. Right now, everyone sees the same thing because the dashboard is accessible as a single environment. It would be better if an Admin could see everything, while a regular employee could only see the files they need for their job. A chart would also be good to the overview section to visually track how many documents the office processes each week, month or year.
